10. ABSTRACT  Documentation and listing of two computer programs intended to provide the Air Force with means of exploring the effectiveness of various detection devices for purposes of interdicting vehicles. The analytical basis for the programs is given in R-1187, which should be used in conjunction with this report. Each program is separately documented, giving all the information needed to operate it. The simulation model simulates detection patterns of vehicles passing through fields of magnetic, acoustic, or seismic sensors, under varying vehicle flow and background (false alarm) conditions. It also provides inputs to the pattern recognition algorithm allowing precise verification of the pattern recognizers' detection ability. The algorithm also accepts real world data, and is adaptive in eliminating from consideration sensors that have provided incorrect information in the past. Together, the programs are a first step toward automating the process of evaluating the sensor information.		11. KEY WORDS  PATTERN RECOGNITION SENSORS COMPUTER SIMULATION SURVEILLANCE

PREFACE

The two computer programs described in this report—a simulation model of vehicle traffic through fields of emplaced sensors, and a pattern detection algorithm of two-way traffic through an emplaced sensor field—were developed as part of Rand's investigation of the employment of USAF tactical air forces for interdiction campaigns. The study was in part responsive to a request by the Commander, Eglin Air Force Base, for assistance in conducting and evaluating the Dune Moon sensor-system tests initiated by former Secretary of Defense Robert McNamara.

The programs described here will provide the Air Force with a means for exploring the effectiveness of various types of emplaced sensor fields. In addition, they permit a first step toward creating an automatic capability that should prove superior to the manual methods currently used to evaluate information provided by fields of emplaced sensors.

Full information to operate both computer programs is provided. The report is intended to assist Air Force and other Department of Defense agencies in exploring the usefulness of emplaced sensor fields, in making decisions concerning their use, and in designing and operating appropriate data-processing techniques. This report should be used in conjunction with Anthony P. Ciervo, *Automatic Track Identification: An Adaptive Pattern Recognition Algorithm*, The Rand Corporation, R-1187-PR, January 1973.

SUMMARY

This report provides the necessary information for using two separate computer programs: (1) a simulation model of vehicle traffic through fields of emplaced magnetic, acoustic, or seismic sensors; and (2) a pattern detection algorithm of two-way vehicle traffic through a field of emplaced sensors.

The simulation model supplies the user with a device to simulate detection patterns of different sensors under varying vehicle-flow and background (false-alarm) conditions. In addition, it provides inputs to the pattern detection algorithm allowing precise verification of the pattern recognizer's ability to detect vehicle flow.

The pattern detection algorithm is designed to accept inputs from the simulation model to allow proper selection of critical parameters. It is also designed to accept real-world data--both actual detections and false alarms--of vehicle flow past fields of sensors. The algorithm is adaptive in that it will eliminate from consideration sensors that provide incorrect information based on previous performance. The pattern detection algorithm, when used with the simulation, will specify the number of vehicle convoys actually detected and the number of vehicle convoys incorrectly identified. Actual times of detection and direction are produced for each supposed convoy identified.

This report should be used in conjunction with Rand report R-1187-PR (see Preface above), which describes the analytical basis for these two computer programs.

PART A: THE SIMULATION MODEL

## I. INTRODUCTION

The simulation model described here deals with the detection of vehicle flow through a field of emplaced sensors. The model permits the user to explore the sensitivity of various sensors to single or multiple vehicle traffic in two directions, simultaneously, through a string of sensors.\* Three levels of background disturbance (false alarms) may be specified by the user. The individual sensor detections--vehicles and false alarms--may be stored on an external medium (tape or disk) for later use by the pattern recognition algorithm (described in Part B), thus serving as a verification and parameter-selection device for that algorithm.

The simulation model was written in the SIMSCRIPT II<sup>†</sup> language for use on The Rand Corporation IBM 360/65 computer. It requires a region size of 76 k bytes and standard input and output devices. Written as an experimental model for that machine, it may require some modifications for other installations.

This part of the report provides a brief description of the processing performed by the simulation model and controlled by the user, some limitations of the model, a detailed description of inputting data to the model, a description of simulation output, and an interpretation of error messages provided by the simulation.

---

\* An analytical treatment of this model is described in R-1187-PR, cited in the Preface.

<sup>†</sup> The particular version was SIMSCRIPT II.5 marketed by Consolidated Analysis Centers, Inc.

## II. PROCESSING PERFORMED

Single or multiple vehicle traffic (convoy) traversing a sensor string in two directions may be simulated with the model. Sensor sensitivity may be specified or based on randomly drawn degradation from some nominal sensitivity, depending on the actual sensor characteristics the user wishes to duplicate. Each sensor is capable of multiple detections as long as a vehicle is within the sensor's sphere of influence and the sensor is capable of detection. Detection would not be possible if the sensor were in the dead-time period immediately following a previous detection.

Realism is introduced into the simulation by permitting sensors to be exposed to several levels of background disturbances (false alarms) that can also result in detections. The output of the model includes statistics on convoys, convoy size, and average detections for each sensor per convoy, per unit time, and per vehicle. Statistics are also presented on false alarms. The model is capable of a visual display of detection patterns and storage (on tape or disk) of detections for use by the pattern detection algorithm.

The user may specify the following:

1. The length of the road segment along which a specified number of sensors are to be equidistantly emplaced.
2. The probability of detection of a vehicle within a sensor's sphere of influence. This is expressed as an isosceles triangular distribution (except in the case of magnetic sensors, which can be specified to have a single detection probability  $p$ ). The accuracy of the detection computation is controlled by an integration step size specified by the user; the smaller the integration step size (i.e., increasing the number of divisions of each triangle), the more accurate the determination of a detection of a vehicle or group of vehicles. However, too large a number of integration increments severely slows simulation execution. We have experienced good results

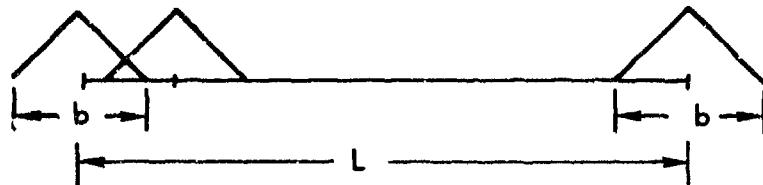

for 1 to 9 vehicle convoys and velocities of 10 to 50 mph using 50 to 75 increments.

3. The base of each triangle, which would represent the sphere of influence of a perfect sensor emplaced in the center of the road segment.
4. A normal distribution of location deviations a sensor would experience if emplaced by air. The simulation can thus introduce the realism of air-delivered sensors by degrading the sphere of influence of each sensor. Further, realism is introduced by allowing the user to specify a probability that the sensor will be destroyed on impact. If the user desires, all triangles representing sensors may have identical characteristics.
5. The time a sensor cannot transmit immediately after a detection.
6. The spacing between vehicles in a convoy as a function of convoy velocity.
7. Convoy generation rate as a Poisson process, the probability of various numbers of vehicles in a convoy, and beta distribution of convoy velocities, which change at each sensor.
8. Three levels of background disturbances (false alarms): ambient, low, and high. These would represent the environment the user wishes to simulate. Each false-alarm level occurs as a Poisson process, with a uniform random duration specified for each. If two false-alarm levels arrive simultaneously, the one with the higher level is considered active. All sensors are exposed equally to false alarms, which are also a Poisson process.
9. Whether a visual-time printout of actual detections is desired. This printout shows vehicle detections (differentiated by direction), false-alarm detections, and first and last vehicle passage past the midpoint of each sensor.
10. The total number of convoys to be simulated or the total time to be simulated.

III. RESTRICTIONS AND LIMITATIONS

The following restrictions and limitations of the model should be observed:

1. Each sensor is equidistantly spaced along the road segment,  $L$ , as illustrated in the diagram below.

Thus, detections may start as early as  $b/2$  before the road segment; likewise, they may end as late as  $L + (b/2)$ .

2. Because of computational restrictions, sensor midpoints may not be closer to one another than  $b/2$ .
3. Although the simulation accommodates traffic flowing in two directions, it does not permit vehicles passing one another in one direction. Whenever a convoy enters a sensor's sphere of influence and there is already a convoy of slower velocity ahead of it, the velocity of the convoy will be set equal to that of the earlier convoy.
4. Computations of detections of convoys going in opposite directions through the same sensor are performed independently.
5. There must be a minimum of three sensors in a string.

#### IV. HOW TO USE THE SIMULATION MODEL

##### INPUT DATA FORMATS

A datum requiring a decimal point is shown by (D); a datum requiring an integer value is shown by (I); and a character datum is shown by (A). Other parenthetical symbols represent the variable name internal to the program.

Data are entered in free format. The only restrictions are that there must be at least one space between entries, and a datum of zero must be entered. Data may be continued on a new card.

##### *New Card--Comments Card*

Any comments, taking up to eighty columns, the user desires to title the output listing.

##### *New Card(s)--Sensor and Control Information*

- a. Print control (PRINT.MAP) (I)

If a graph of detections and false alarms is desired as the simulation progresses, enter 1. Otherwise, enter 0.

- b. Number of convoys (MAX.NBR.CONVS) (I)

The maximum number of complete convoy passages desired before stopping the simulation.

- c. Time control (MAX.TIME) (D)

The maximum length of simulated time (minutes) allowed for the simulation. Simulation halts at the first completed convoy passage whose completion time is greater than this value.

- d. Road segment length (ROAD.LGNTH) (D)

Length of road segment in meters.

- e. Number of sensors (N.SENSORS) (I)

Number of equally spaced sensors along the road segment. Must be greater than 2.

f. Integration increments (I)

Enter 1, if magnetic sensors are desired; otherwise, enter the number of triangular distribution increments.

g. Maximum permitted triangle base (NOMINAL.BASE) (D)

b, base length, in meters, of a perfect sensor dropped in the center of the road.

h. Destruction probability (PROB.DEAD) (D)

The probability ( $0 < p < 1$ ) a sensor will be destroyed on impact.

i. Normal distribution standard deviation (STD.DEV) (D)

The standard deviation in meters of the specified normally distributed drop pattern of sensors about the road.

j. Sensor dead time (DEAD.TIME) (D)

The time, in minutes, that the sensor cannot transmit after a detection. Must be greater than zero.

k. Coefficient (AREA) (D)

(1) If the sensors to be simulated are magnetic sensors, enter the probability of the sensors' ability to detect. Must be less than or equal to 1.0.

(2) For runs where a constant base is desired for all sensors, enter the height of the sensor triangle. Each base will be the value entered for maximum base in item g above.

(3) For simulation of sensors distributed about the road, enter the coefficient  $c_1$ .\*

l. Coefficient two (C.2) (D)

For simulation of sensors distributed about the road, enter the coefficient  $c_2$ .\* Otherwise, enter 0.0.

---

\* See R-1187-PR for a discussion of how these constants should be computed.

m. Random seed (SEED.V(8)) (I)

Enter any of the ten random seeds shown in Appendix A. The sequence of random numbers thus started selects the distribution of sensors about the road. On subsequent runs, entering the same number will yield the same random number stream, or entering a new number will yield a different stream.

n. Base control flag (RAN.NER) (D)

If all sensor triangles are to have the same base, enter 1.0. The base will be that in item g above. Then enter the height of the triangles in item k (2) above. Otherwise, enter 0.0.

o. Truck spacing (SPACE.FACTOR) (D)

Enter the spacing, in meters, desired between trucks for each kilometer per hour of convoy velocity.

p. Constant convoy generation flag (CONSTANT.CON) (I)

Entering 1 will cause all convoys to be generated with a constant interarrival time at the specified mean rate. Otherwise, enter 0.0.

New Card(s)--Trucks in Convoy Distribution

Pairs of Values

1st Cumulative prob.,  $p_1$  (D) of number of trucks,  $T_1$  (I)

2d Cumulative prob.,  $p_2$  (D) of number of trucks,  $T_2$  (I)

: : : :

nth Cumulative prob.,  $p_n$  (D) of number of trucks,  $T_n$  (I)

Enter an asterisk (\*) after  $T_n$ .

New Card(s)--Westbound Convoy Information

a. Convoy rate (RATE.CNV) (D)

Mean of a Poisson distribution. The average number of convoys generated per minute.

- b. Mean convoy velocity (MEAN.VEL) (D)  
Mean of a beta distribution. The average velocity of the convoys in kilometers per hour.
- c. Modal convoy velocity (MODE.VEL) (D)  
Mode of a beta distribution. The modal velocity of the convoys in kilometers per hour.
- d. Upper bound on velocity (UPPER.BND) (D)  
The highest possible velocity of a convoy in kilometers per hour.
- e. Lower bound on velocity (LOWER.BND) (D)  
The lowest possible velocity of a convoy in kilometers per hour. Must be greater than zero.
- f. Direction name (DIR. SYMBOL) (A)  
The convoy direction may be designated by using any four letters. For convenience, WEST is suggested. Such a convoy will always start at sensor 1.

*New Card(s)--Eastbound Convoy Information*

Enter items a through e as for the westbound convoy. The values may be different. The entry for f can be EAST or any other four-letter symbol. Convoys for this direction always start at the nth sensor.

*New Card(s)--False-Alarm Information*

- a. Ambient arrival rate (LAM) (D)  
This is the arrival rate of false alarms of the lowest density (level 1). It is the mean of a Poisson process. It is entered as number per minute for a single sensor.
- b. Medium arrival rate (LAM) (D)  
Arrival rate of false alarms of the medium density (level 2); false alarms in number per minute for a single sensor.

c. Maximum-level, 2-burst length (UB) (D)

Upper bound of a uniform distribution determining burst length of a level-2 false alarm in minutes.

d. Minimum-level, 2-burst length (LB) (D)

Lower bound of the uniform distribution that determines burst length of a level-2 false alarm in minutes.

e. Arrival rate of level-2 bursts (GAM) (D)

The rate at which bursts of level 2 arrive. The mean of a Poisson process in number per minute.

f. High arrival rate (LAM) (D)

Arrival rate of false alarms of the highest density (level 3); false alarms in number per minute for a single sensor.

g. Maximum-level, 3-burst length (UB) (D)

Upper bound of a uniform distribution that determines burst length of a level-3 false alarm in minutes.

h. Minimum-level, 3-burst length (LB) (D)

Lower bound of the uniform distribution that determines burst length of a level-3 false alarm in minutes.

i. Arrival rate of level-3 bursts (GAM) (D)

The rate at which bursts of level 3 arrive. The mean of a Poisson process in number per minute.

#### A SAMPLE DATA DECK

The following figure (from Appendix B) shows a sample data deck punched from the above input data formats:

THIS IS AN EXAMPLE OF THE SIMULATION MODEL 2 DEC 1972  
1 20 1000.0 1000.0 5 50 250.0 0.2 20.0 0.15 40.0 1000.0 8108509  
0.0 1.0 0  
0.1 1 0.3 2 0.4 3 0.6 4 0.9 5 1.0 6 \*  
0.1 24.0 20.0 35.0 15.0 WEST  
0.06 24.0 20.0 35.0 15.5 FAST  
0.5 1.5 6.0 0.5 0.2 3.0 0.5 0.01 0.05

A 1000-meter road segment has been selected on which five sensors have been equidistantly spaced and dropped randomly. Vehicles traverse the road segment in two directions.

#### INTERPRETING THE SIMULATION OUTPUT

Figure 1 shows a sample of the description of the input data deck and some of its ramifications. This description is produced by each simulation run. The first line after the heading is a repeat of the comment card in the data deck. The second line gives the data controlling the length of the simulation in convoys generated and/or total time.

Fig. 1 — Description of input data deck

Under SENSOR PARAMETERS are the length of the road segment in meters and the number of sensors. The second line shows the base size of a perfect sensor emplaced on the road segment, followed by the two coefficients used to determine the height of the triangular distribution of the represented sensor. The next line indicates the number of increments each triangle will have for computing the probability of detections. The next three lines contain several items: the user-inputted probability that a sensor will be destroyed on impact, the standard deviation (meters) of the normal distribution that is used for randomly selecting the distance from the road that a sensor is emplaced after being dropped, the dead time of the sensor, and the random seed. The random seeds determine the starting point of random draws from the normal distribution.

SENSOR ATTRIBUTES are the resulting characteristics of each sensor after its distance from the center of the road is randomly selected from the normal distribution. The effective base is shown for each sensor. A zero indicates the sensor was destroyed on impact or landed too far from the road to be effective. If it was destroyed on impact (shown by a 1 in the column labeled DEAD), it will never transmit false alarms. The column labeled SLOPE X DELTAS gives the factor that, when multiplied by the position of a vehicle in the sensor field of influence, will yield the probability of detection at that point. The column labeled DELTAS(M.) gives the width of each increment of the triangular distribution. During the simulation, a vehicle moves this increment before a calculation of the probability of detection is made. The column labeled AREA is the area of each sensor's triangular distribution and represents the sensitivity of the sensor for detecting vehicles of a given velocity.

Under CONVOY INFORMATION the distance between trucks in a convoy comes directly from the input data, as does the size of convoy distribution. Each time a convoy is generated, a uniform random variate is drawn to determine the number of trucks in the convoy. For example, if a number between 0.6 and 0.9 is drawn, the convoy will have five trucks, or if a number between 0.0 and 0.1 is drawn, it will have one truck.

The next two paragraphs in Fig. 2 reflect the information on convoys traveling in the west and east directions and start with the mean rate (Poisson process) at which convoys will be generated, followed by the beta distribution information on convoy velocity. K1 and K2 are the parameters of the distribution computed from this information. Each time a convoy starts through a sensor, its velocity is computed by random sampling from this distribution.

Under FALSE-ALARM INFORMATION, the three alarm levels are shown (1 = ambient, 2 = low or medium, 3 = high). They must have increasing ALARMS/MIN, which is the mean of the Poisson process that generates false alarms to sensors when a particular level is on. The ARR/MIN column gives the mean arrival rate (Poisson process) of each level of false alarms. Of course, if neither alarm-level 2 nor 3 is on, level 1 (ambient) will be. MIN BURST (MIN) and MAX BURST (MIN) are the inputted minimum and maximum times (minutes) of the uniform distribution of the duration of level-2 and level-3 false alarms.

Figure 2 shows an example of the printed output the user can obtain by exercising the print-control option (field "a" of the sensor- and control-input data). The simulated time in minutes is shown down the left side. The increment of time is the sensor dead time. In the column for each sensor, E or W represents a vehicle detection for a convoy traveling from the east or west. The + or - represents the passage of the first and last trucks of the convoy past the midpoint of a sensor (+ is for convoys from the east, and - for convoys from the west). Usually these signs are paired, but occasionally only one is shown. A single occurrence is the result of (1) the passage of only a single vehicle or (2) a convoy speed that is too fast relative to the time increments printed. The symbols 1, 2, \* represent false alarms of level 1, 2, and 3, respectively.

An example of summary statistics relating to false alarms is given in Fig. 3. SYSTEM FALSE ALARMS are the number of times each alarm level was on during the simulation. This item is shown under NO. OF BURSTS. The average length of time each was on is shown under AVG. BURST LENGTH (MIN). The number of times each level was on divided by total simulated time is shown under AVG BURST ARR/MIN. For each sensor the average

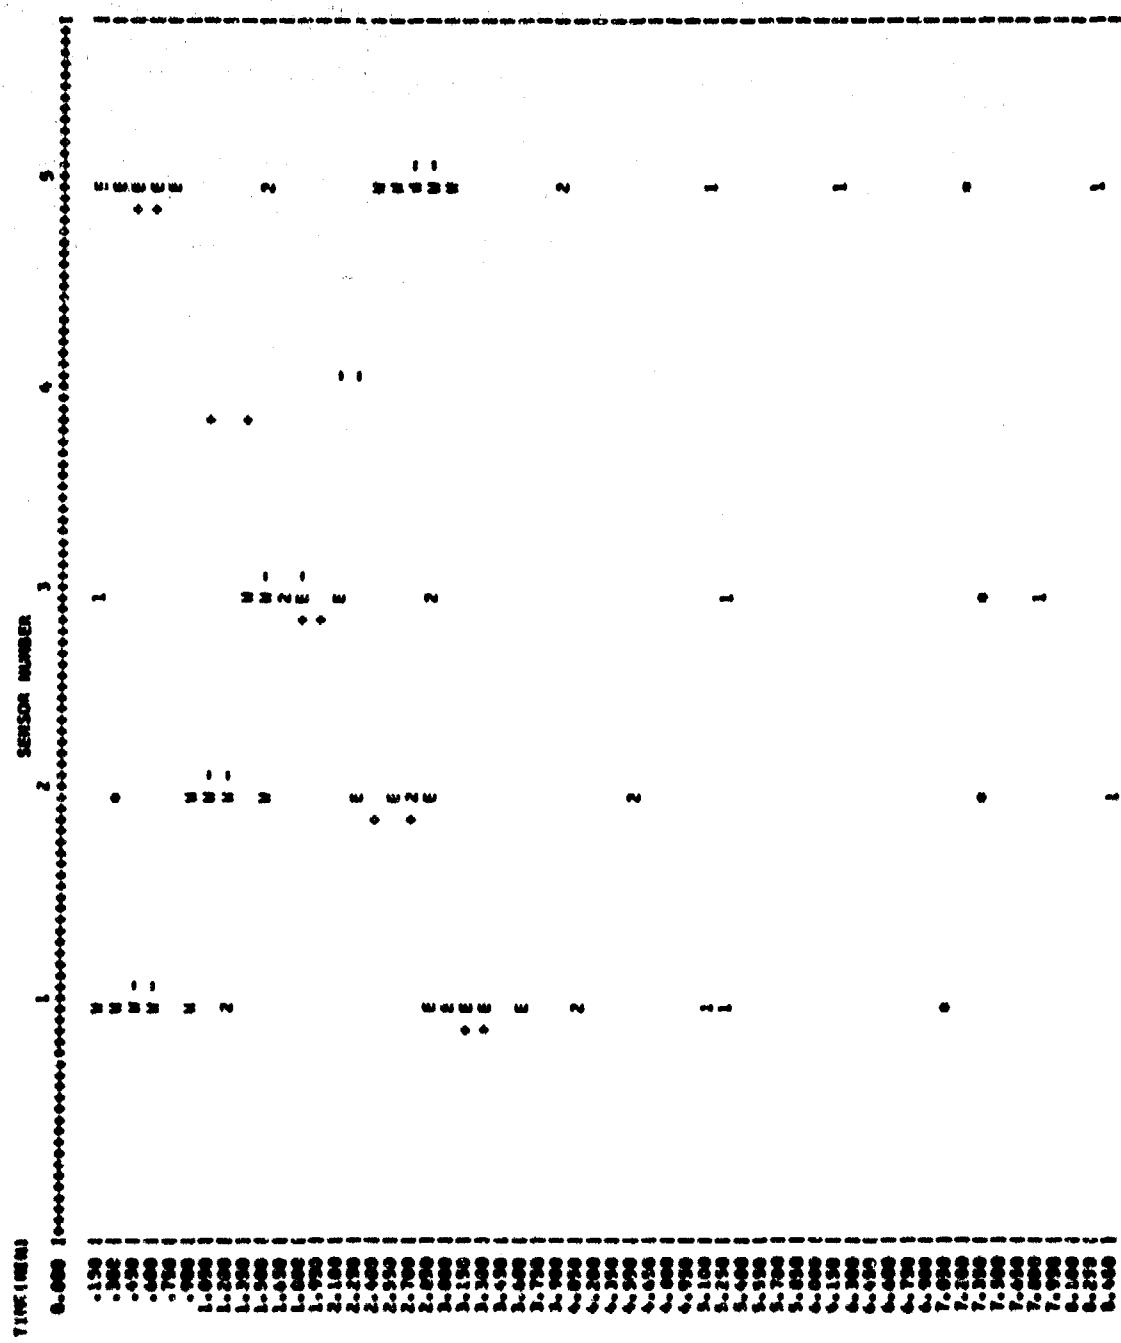

Fig. 2 — Printed output option

caused by vehicles

#### INTERPRETING ERROR MESSAGES

The simulation makes basic checks on the input data for compatibility. If some of the input rules have been violated, error messages of the following type appear after the erroneous data is read:

??? ERROR IN ABOVE LINE.

The processing then halts. The user thus has the incorrect value and an indication that it is incorrect. He should examine the data input to see which rule was violated. Examples of violations are negative road length, a lower alarm rate for level 3 than level 2, and the probability of destroying a sensor on impact greater than 1.0.

#### THE OUTPUT FILE

An output file, in the proper format for use by the detection algorithm, is produced as normal output of the simulation. It contains all actual detections (as well as those caused by false alarms), convoy size, and entry/exit times of convoys into/out of the sensor string. See Appendix D2 for the format of the output file.

#### ADDITIONAL INFORMATION

Appendix B contains an example of a fully setup data deck for execution of a simulation on the Rand IBM 360/65 computer installation. Appendix C is a full source listing of the entire program.

PART B: THE PATTERN DETECTION ALGORITHM

Preceding page blank

I. INTRODUCTION

The pattern detection algorithm<sup>\*</sup> presented here will identify vehicle tracks in two directions through a field of emplaced sensors. The algorithm is an adaptive detection mechanism--it continually measures the performance of each sensor in the string, giving more weight to information from reliable sensors and less to unreliable sensors. When a sensor is deemed very unreliable by a user-inputted criterion, it is dropped from consideration entirely.

The algorithm is designed to operate from data provided by the simulation model described in Part A or from real-world data. The algorithm is programmed in FORTRAN IV for the Rand IBM 360/65 installation and requires 178 k bytes of core.<sup>†</sup>

Part B of this report provides a brief description of the processing performed by the algorithm, some limitations of the algorithm, a detailed description of how to input data to the model, a description of typical algorithm output, an interpretation of error messages provided by the program, and the format required for inputting actual sensor detection data.

---

<sup>\*</sup>Detailed analytical description of the algorithm is provided in R-1187-PR.

<sup>†</sup>Use of this program at other installations that do not have graphic capability would require removal of the graphic routines and other minor modifications.

## II. PROCESSING PERFORMED

The algorithm begins by examining clusters of activations on a sensor. If there are at least  $\omega$  activations no more than  $\beta$  minutes apart, the cluster is defined as a *valid strip* and a window is opened on the adjacent sensors (see Fig. 6, p. 25). The window length is primarily a function of anticipated vehicle velocity. Thus a conjectured vehicle track (trajectory) is initiated. A valid strip intersecting a window is defined as an *admissible strip*. If a conjectured vehicle track contains at least  $M$  admissible strips, the trajectory is confirmed as a vehicle track. Each admissible strip in a confirmed vehicle track is called an ASTI (admissible strip contributing to a track identification). The adaptive logic of the algorithm uses the information on valid strips, admissible strips, and ASTIs for each sensor over time periods of length  $B$  to determine the sensor's reliability. High-reliability sensors are given more weight and low-reliability sensors less weight in confirming vehicle tracks. A sensor that continues to have low reliability is eventually eliminated from the string. Thus, on the basis of prior information, the algorithm is capable of adapting its detection ability.

When used in conjunction with the simulation model output, the algorithm will provide statistics on the actual number of convoys detected and missed. The size of convoy, the weights of each sensor for each update, and the number of vehicle tracks identified that were not caused by vehicles will be determined. Graphic output also allows the user to observe the step-by-step process of identification and the actual time a particular track is confirmed.

The user may specify the following:<sup>\*</sup>

1. The anticipated average, minimum, and maximum velocities of convoys traversing the sensor string in either direction.
2.  $\beta$ , the maximum interval between activations in a valid strip.

---

<sup>\*</sup>See R-1187-PR for precise definition of terms and analytical treatment of the algorithm.

3.  $\omega$ , the minimum number of activations in a valid strip.
4.  $M$ , the number of admissible strips required for a trajectory confirmation.
5. The length of the road segment.
6. The number of sensors in the string and their position along the string.
7.  $B$ , the number of trajectories (track identifications) to be confirmed before updating sensor performance information (weights).
8.  $\rho$ , the back weight for the smoothing function.
9.  $C$ , weight below which an inferior sensor is removed from the string after  $D$  consecutive weight updates.
10.  $W$ , a lower bound on sensor weights for confirming vehicle tracks. The sum of the sensor weights for those sensors contributing admissible strips must be greater than  $W$  to confirm a trajectory.
11. A control parameter allowing visual graphs of sensor activity, window activity, track-identification times, false alarms, and vehicle activations.

### III. RESTRICTIONS AND LIMITATIONS

As currently coded, the following maximums must be adhered to:

1. B, the number of vehicle tracks to be confirmed (maximum of 50) before updating sensor performance information (weights).
2. Maximum of 15 sensors. (Can be increased to 50 by redimensioning all common arrays in the program. Sufficient information is provided in the MAIN routine for a programmer to make the change.)
3. Maximum of 20 trucks per convoy.

As might be expected, a large number of patterns are possible from various combinations of valid and admissible strips. Every attempt has been made to anticipate anomalous behavior of various trajectory paths.

Figure 6a shows what might be regarded as the most typical behavior and is to be expected in the majority of vehicle tracks. A valid strip on the first (or a subsequent) sensor opens a window on the second sensor in which a valid strip falls, thus opening a window on the third sensor, and so on. Finally, the vehicle track is confirmed.

Figure 6b presents a case in which a valid strip fails to fall in a window. The window is just extended to the average convoy velocity defined by the user. (This illustration requires three admissible strips to confirm a vehicle track.)

Figure 6c shows that a vehicle track once begun will be continued until the end of the string. Although this may seem unnecessary, since a vehicle track with only one admissible strip can never be confirmed, it results in faster computation time and causes no problems.

Figure 6d illustrates a condition that occurs occasionally. At the second sensor two valid strips fall in the same window, and their windows on the subsequent sensor overlap. In this case the program considers the extremes as one large window.

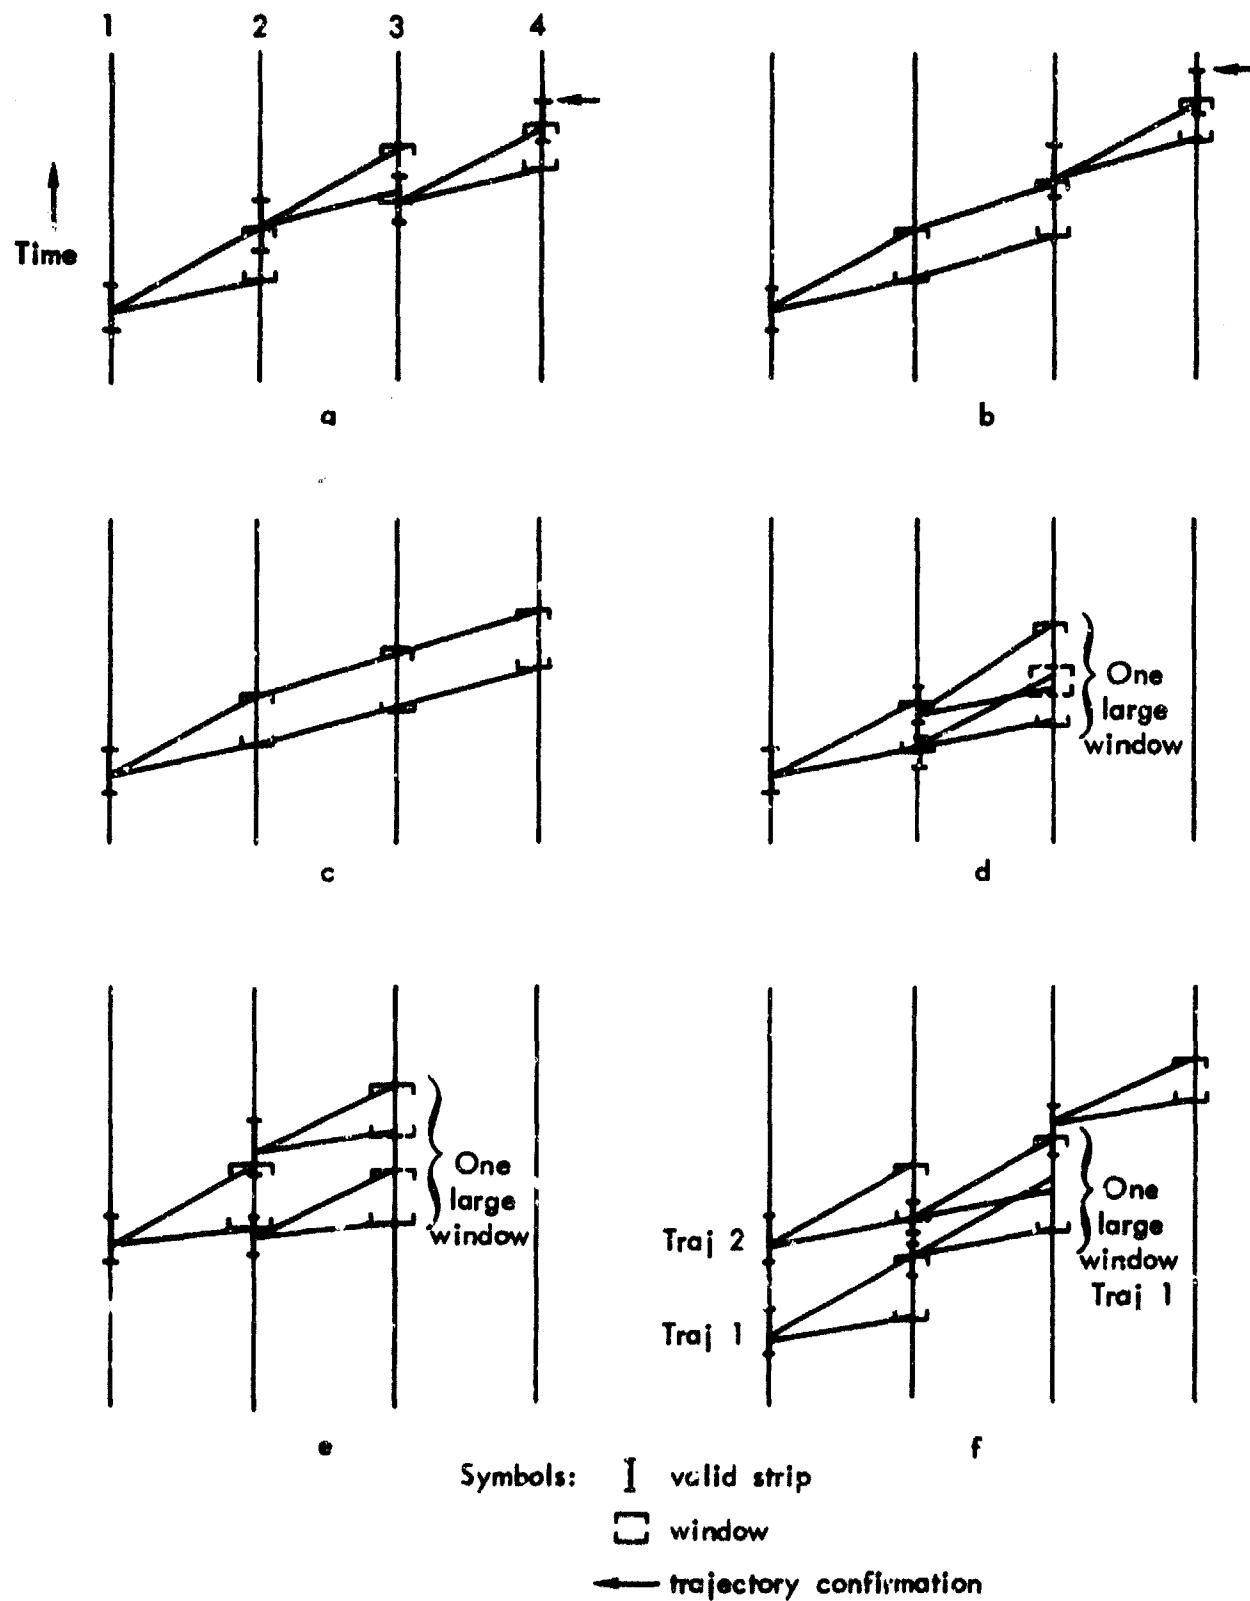

Fig.6 — Illustration of program's handling of anomalous behavior

Figure 6e shows a similar condition, but the windows on the subsequent sensor do not overlap. The extremes are still treated as one large window--except if the lower window was closed before the upper window was opened. (Windows are scanned for possibility of closure by any sensor activation and are closed providing the activation is at a later time than the time of the upper portion of the window.) In this situation two separate vehicle tracks are continued along.

Figure 6f illustrates a rare occurrence. Two separate trajectories are so close that valid strips in later windows create overlapping windows on a subsequent sensor. When this occurs, one large window is created and given the identification of the lower vehicle track. Any previous admissible strips of the upper vehicle track are transferred to the lower vehicle track.

IV. HOW TO USE THE PATTERN DETECTION ALGORITHM

SPECIFYING THE INPUT DATA

A datum requiring a decimal point is shown by (D); a datum requiring an integer value is shown by (I). All data entries must fall within the column limitations specified. All integers must be right justified. Parenthetical symbols are the internal symbols in the program.

*Card 1--Comments*

Any comments the user desires to make to identify the run.

*Card 2--Input Parameters*

Cols.

1-2	Integer 1 for identification.	(I)
3-10	Westbound average convoy velocity in kilometers per hour (AVGVEL(1)).	(D)
11-20	Westbound maximum convoy velocity in kilometers per hour (BBWND(1)).	(D)
21-30	Westbound minimum convoy velocity in kilometers per hour (UPWND(1)).	(D)
31-40	Eastbound average convoy velocity in kilometers per hour (AVGVEL(2)).	(D)
41-50	Eastbound maximum convoy velocity in kilometers per hour (BFWND(2)).	(D)
51-60	Eastbound minimum convoy velocity in kilometers per hour (UPWND(2)).	(D)
61-70	B, maximum time in minutes permitted between detections in a valid strip (BETA).	(D)
71-80	C, weight below which a sensor is considered for elimination from the string (CSENS).	(D)

*Card 3--Input Parameters (continued)*

Cols.

1-10	W, a lower bound on sensor weights. The sum of the sensor weights for those sensors contributing admissible strips must be greater than W to confirm a trajectory (WCAP).	(D)
11-20	Road segment length in meters (SEGLNT).	(D)
21-30	M, the percent of live sensors required to contribute admissible strips for trajectory confirmation (PCTSEN).	(D)
31-40	B, the number of trajectories to be confirmed (maximum of 50) before updating weights (NB).	(I)
41-50	D, number of consecutive time periods that a sensor weight is below C before it is eliminated from the string (ND).	(I)
51-60	w, the minimum number of detections, no more than 8 minutes apart, required to define a valid strip (IWCNT).	(I)
61-70	The number of sensors (maximum of 15) in the string (NSENSR).	(I)
71-78	When requesting SC-4060 graphs, specify the number of simulation minutes (multiples of ten minutes only) to be portrayed on each graph (GRAPH).	(D)
79-80	If graphs are desired, enter 1; otherwise, 0 (KAGRAF).	(I)

*Card 4--Input Parameters (continued)*

Cols.

1-2	If graphs are desired and you wish to see truck detections, false alarms, and windows separately identified, enter 1. If the graph is to show only all impulses with no windows, enter 0 (NOWIND).	(I)
3-8	p, the back weight for the smoothing function (RHO).	(D)

### Card 5--Distance between Sensors

cols.

1-2	The integer 2 to identify the card.	(I)
3-10	Distance between the 1st sensor and the 2d in meters.	(D)
11-20	Between 2d and 3d.	(D)
21-30	Between 3d and 4th.	(D)
31-40	Between 4th and 5th.	(D)
41-50	Between 5th and 6th.	(D)
51-60	Between 6th and 7th.	(D)
61-70	Between 7th and 8th.	(D)
71-80	Between 8th and 9th.	(D)

If there are more than 9, start over on a new card (Cols. 1-10, 11-20, 21-30, etc.). Caution: The sum of the distances must equal precisely the length of the road segment.

## A SAMPLE INPUT DECK

The input deck (shown in Appendix E) is specified in such a way that the detection algorithm will use the output information of the simulation that was stored on tape from the example shown in Appendix B. The following figure is an excerpt from the deck in Appendix E:

**Col.2** THIS IS AN EXAMPLE OF THE PATTERN DETECT. ALGOR. USING SIMULATED DATA 2/12/72  
 1 24.0 35.0 15.0 24.0 35.0 15.0 0.40 5 60.0 1  
 0.5 1000.0 .67 5 3 3 5 0.05  
 0 1.0 2 250.0 250.0 250.0 250.0

If the pattern detection is to be run with data other than provided by the simulation, the input tape of activations must be formatted as shown in Appendix D1 for actual data or in Appendix D2 for experimental data.

INTERPRETING THE PROGRAM OUTPUT

Figure 7 shows the first page of the output, which is a summary of all the input data. Notice on the fifth line that at least 0.67 of the sensors in the string are needed to confirm a vehicle track. The user should be aware that the computation taking place involves truncation of the fractional part of the number. Thus  $0.67 \times 5 = 3$ . This is important, for if 0.66 were specified and two sensors were dropped from the string as unreliable, then  $0.66 \times 3 = 1$ , and the program would halt with an error message, since at least two sensors are obviously required to identify a track direction. The eighth line refers to dropping hypoactive sensors, meaning any unreliable sensors, as determined by the adaptive logic. GRAPHING CONTROL: 1 indicates that there will be graphs produced. A zero would indicate no graphs. WINDOWS ON (-1) indicates that the graphs will discriminate between vehicle detections and false alarms, will display all windows, and will display confirmed vehicle tracks. The smoothing constant is the back weight  $\rho$ . The distance between sensors is shown and will always have 0.0 for the first sensor.

Fig.7 — Summary of input data

Figures 8a and 8b show an example of output that gives all relevant information on the progress of the algorithm. If input data are from the simulation, information is shown on convoys. The SENSR column indicates the sensor being described. The CLOSE-OPEN columns show the time of the upper and lower portions of the window on the sensor. For example, the first entry shows a window was opened at 0.764 minutes and closed at 1.335 minutes for sensor 4.

The column labeled DIR shows the direction of the vehicle track. 1 is eastbound and 2 is westbound. TRAJ NO. shows the internal trajectory number assigned to the vehicle track. Since vehicle tracks can be in two directions, there is always a westbound and eastbound vehicle track with the same number. An interested user could follow the progress of a vehicle track using its number and directions. For example, trajectory 1, direction 1, opened windows on sensor 2 at 0.986 minutes, on sensor 3 at 1.525 minutes, on sensor 4 at 2.086 minutes, and on sensor 5 at 2.711 minutes. A vehicle track was confirmed at 3.283 minutes for this trajectory, which happened to be a convoy of five trucks (NRCNDT(5)).

The convoy information portion of the printout (for simulation data only) shows the time a convoy enters and leaves the string, and the number of trucks in the convoy. The CONVOY NO. and DIR columns identify the particular convoy, and the TRUCKS column shows the number of trucks in the convoy. If there is no entry in this column, it means that a convoy is leaving the string. For example, the first truck of convoy 1, direction 1, entered the string at time 0.0 with five trucks, and the last truck of the convoy left the string at 3.183 minutes.

The algorithm is able to tell if a particular convoy is detected by seeing if there is any overlap between the last trajectory window and the convoy transit time. For the example we have been following, the convoy left the string at 3.183 minutes, and the last window of the trajectory opened at 2.711 minutes and closed at 3.283 minutes. Thus the algorithm assumes that the confirmed vehicle track is for that convoy.

Figure 8b shows that, as requested, weights are updated after every five trajectory confirmations. The number of valid strips and

Fig. 8a — Output on progress of algorithm

**Fig. 8b** — Output on progress of algorithm

ASTIs on each sensor are shown, as are the updated  $w_i$  and  $w'_i$  (resulting from smoothing). In this particular example no sensors were dropped from the string; if any had been dropped, they would be shown at this point.

Figure 9 is an example of summary output provided on convoy detections. This has meaning only when input data come from the simulation model or experimental data in the format shown in Appendix D2. For each convoy size the number of convoys generated and detected are shown. We see that of the 20 generated convoys 17 were detected by the algorithm. There were 18 confirmed trajectories. Thus one was a phantom, most likely resulting from a combination of truck detections and false alarms.

*** CONVOY DETECTION SUMMARY ***		
CONVOY SIZE	NO. GENERATED	NO. DETECTED
1	2	1
2	6	4
3	2	2
4	2	2
5	3	3
6	3	3
7	0	0
8	0	0
9	0	0
10	0	0
11	0	0
12	0	0
13	0	0
14	0	0
15	0	0
16	0	0
17	0	0
18	0	0
19	0	0
20	0	0
TOTALS :	20	17
PHANTOM TRAJ =	1	TOTAL CONFIRMED = 18

Fig. 9 — Summary of convoy detections

A summary of unsmoothed sensor weights at each time period is shown in Fig. 10. The mean and standard deviations of the weights are shown for each sensor. A similar summary will follow this one for smoothed weights containing similar information.

Figure 11 is an example of the optional graphic output of activations on each sensor with no discrimination as to type of activation (false alarm or vehicle), and without windows. We have found this output useful in that it is similar to what a human observer would see.

\*\*\* SENSOR WEIGHTS BY TIME PERIOD \*\*\*

TIME PERIOD	1	2	3	4	5	SENSOR
1	0.200	0.200	0.200	0.200	0.200	
2	0.250	0.250	0.250	0.0	0.250	
3	0.278	0.278	0.167	0.0	0.278	

MEAN : 0.2426 0.2426 0.2056 0.0667 0.2426  
STD DEV : 0.0394 0.0394 0.0419 0.1155 0.0394  
(THESE WEIGHTS ARE NOT SMOOTHED)

Fig. 10 — Summary of sensor weights

A comparison may thus be made between the accuracy of humans and that of the algorithm in detecting vehicle tracks.

Figure 12 is an example of the same graphic output as is shown in Fig. 11 but with discrimination of activations, windows, convoy midpoint passage, and trajectory confirmation shown. The + sign represents activation caused by vehicles, and the \* symbol those activations caused by false alarms. The + signs to the right or left of the sensor represent passage of the first and last truck of the convoy past the sensor midpoint. The [ ] symbols represent windows for conjectured vehicle tracks moving to the left, and the ^ \ symbols, windows of conjectured vehicle tracks moving to the right. The + symbol represents vehicle track confirmation.

#### INTERPRETING ERROR MESSAGES

Correct the input card for the following errors:

##### Error

- 5 ID on card 2 is not 1 in Col. 2.
- 10 Average velocity of westbound convoys is less than or equal 0 (cc<sup>\*</sup> 3-10, card 2).
- 15 Average velocity of eastbound convoys is less than or equal 0 (cc 31-40, card 2).
- 20 Maximum velocity of westbound convoys is less than or equal 0 (cc 11-20, card 2).
- 25 Maximum velocity of eastbound convoys is less than or equal 0 (cc 41-50, card 2).

\* cc means card column.

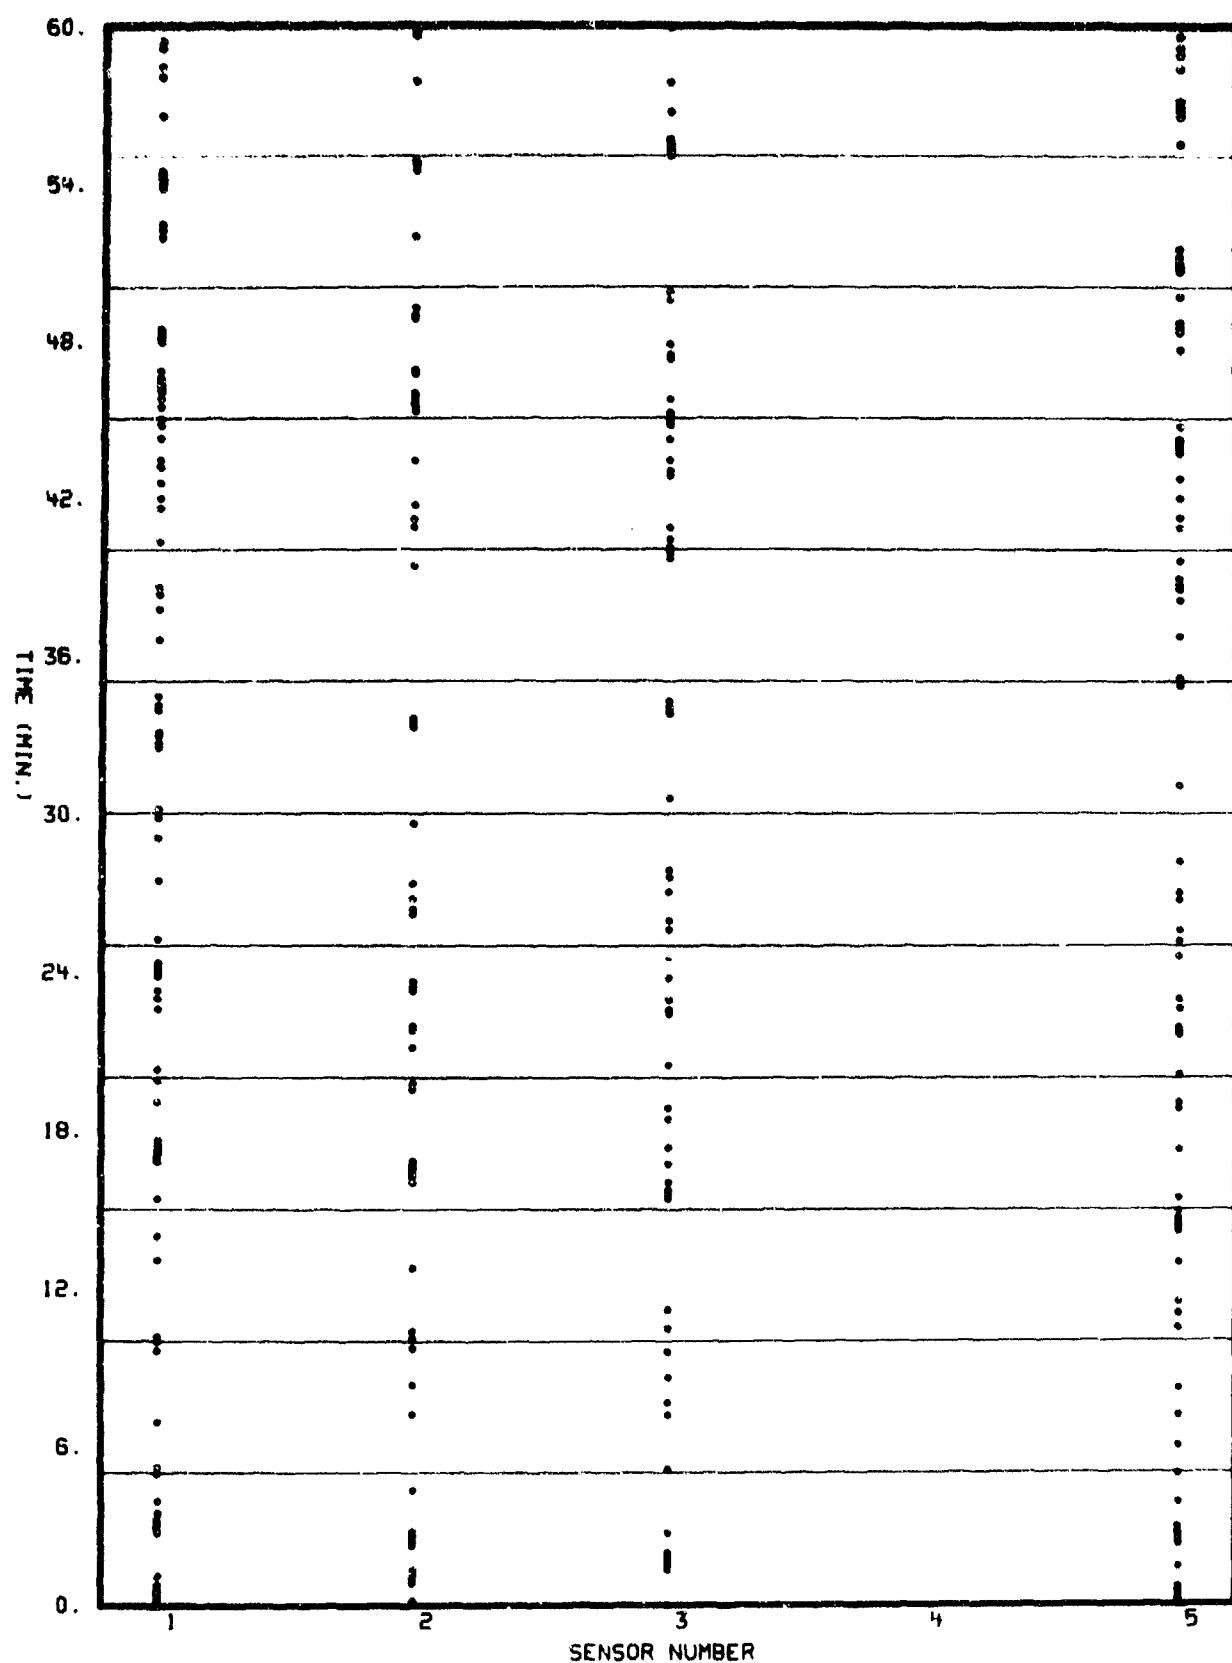

Fig.11 — S-C 4060 graphic output (no windows shown)

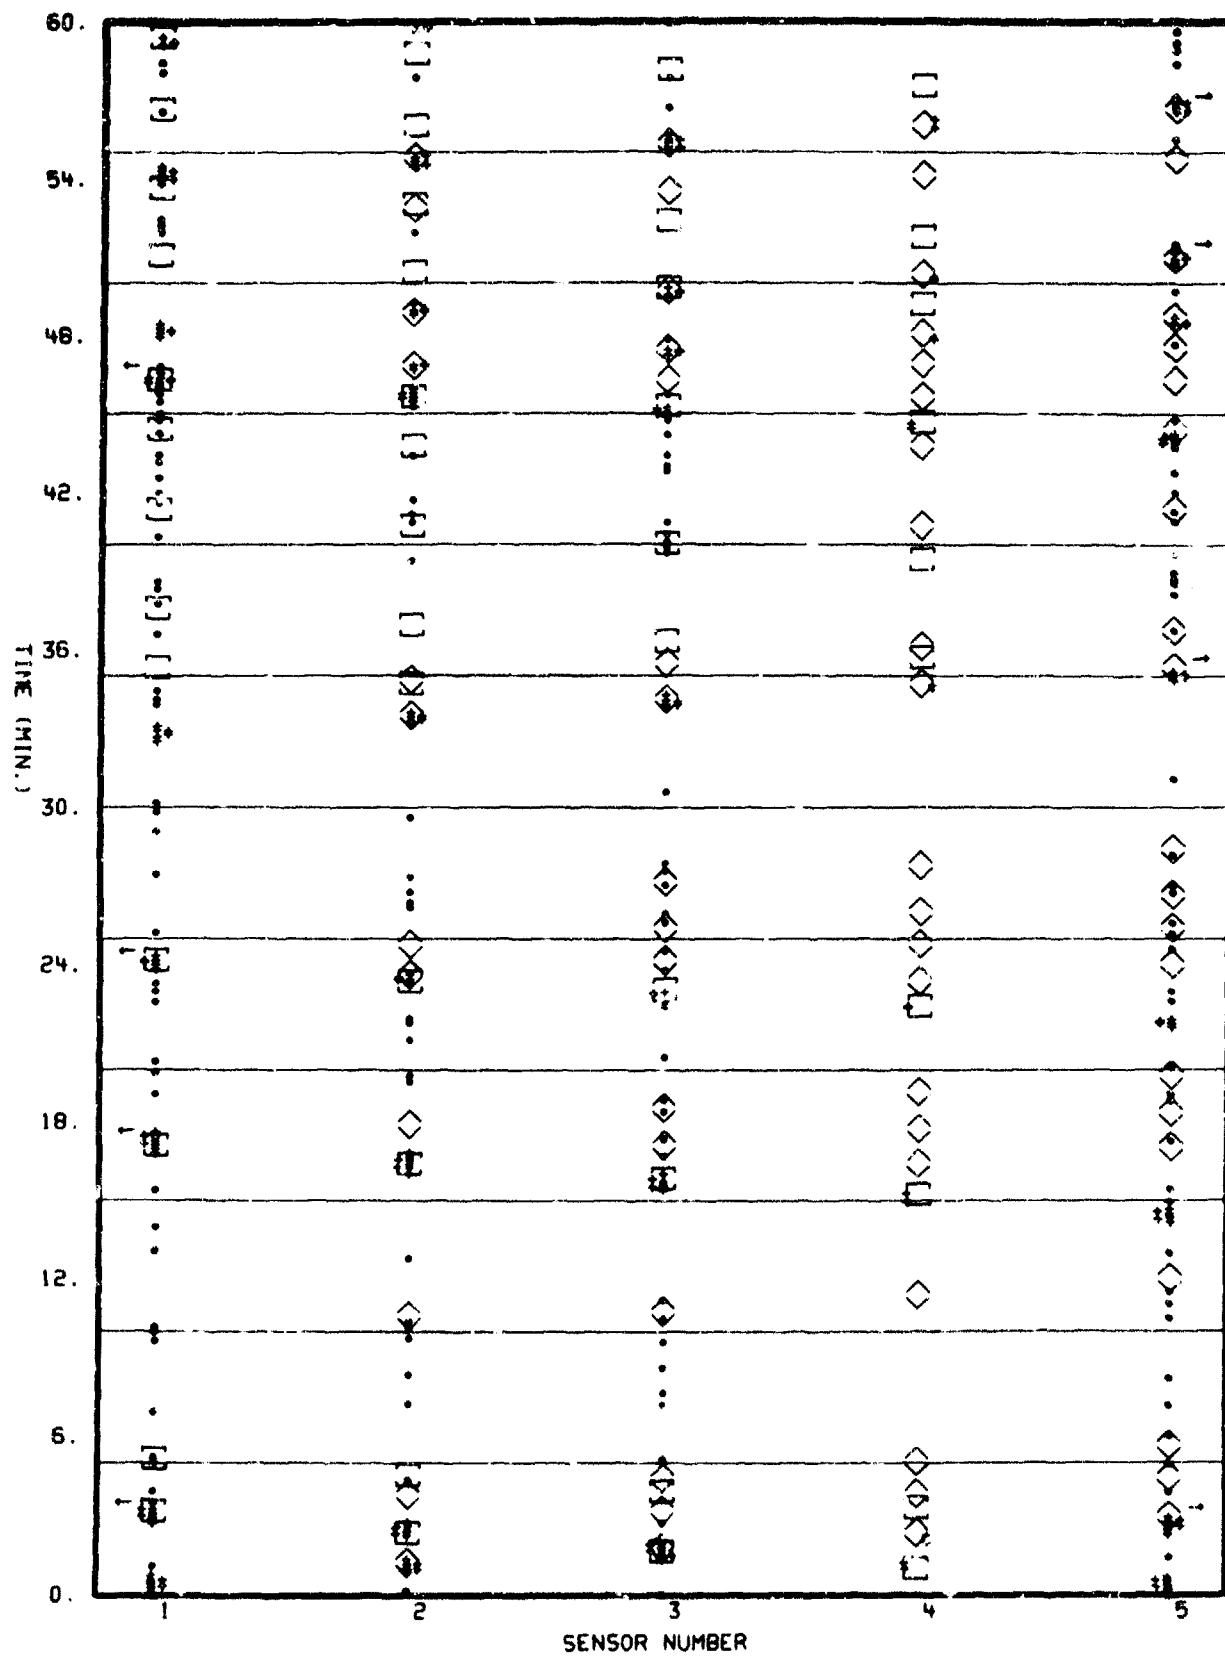

Fig. 12 — S-C 4060 graphic output (windows shown)

Error

- 30 Minimum velocity of westbound convoys is less than or equal 0 (cc 21-30, card 2).
- 35 Minimum velocity of eastbound convoys is less than or equal 0.
- 40 S is less than or equal 0 (cc 61-70, card 2).
- 45 C is less than or equal 0 (cc 71-80, card 2).
- 50 W is less than or equal 0 (cc 1-10, card 3).
- 55 Road segment is less than or equal 0 (cc 11-20, card 3).
- 60 M results in less than 2 sensors (cc 21-30, card 3).
- 65 B is less than or equal 0 (cc 31-40, card 3).
- 70 D is less than or equal 0 (cc 51-60, card 3).
- 72 The number of sensors in the string is greater than the maximum permissible (cc 61-70, card 3).
- 75 w is less than or equal 0 (cc 51-60, card 3).
- 80 The sum of the distances between sensors does not exactly sum to the road segment length (card 5).
- 117 The user has asked for more minutes of simulated time than a graph can display. Reduce the number in cc 71-78, card 3.  
(Must be a multiple of 10.)

The following errors are catastrophic, and processing halts unless otherwise stated. Many call for diagnosis by the maintenance programmer. We have never experienced these types, but they were included because if any were to be encountered, the results would be catastrophic.

Error

- 200 A value in the IDROP array has gone negative. The value, the sensor number, and simulated time the error was detected are shown. The maintenance programmer must diagnose.
- 210 Same as 230 but in the CHKWIN routine.
- 220 Same as 260 but in the CHKWIN routine.
- 230 A value in the IDROP array has gone negative; it is detected in the CHKOVL routine. The sensor number and value are shown. The maintenance programmer must diagnose.

Error

- 240 The direction constant K is improper; it is detected in the CHKOVL routine. The value is shown. The maintenance programmer must diagnose.
- 260 A value of the NOPENT array has been detected as negative in the CHKOVL routine. The trajectory number, direction number, and value are shown. The maintenance programmer must diagnose.
- 270 A value of the NASTC array has been detected as negative in the CHKOVL routine. The values of NEJ, K, I2, and NASTC are shown. The maintenance programmer must diagnose.
- 300 The number of trucks in a convoy has been read in as a negative value from the external device (tape or disk). Thus the input data are faulty. The negative value convoy number and time of activation are shown. This error occurred in the READ routine.
- 410 A value in . IDROP array has gone negative, as detected in the TRAJCM routine. The value, the sensor number, and KL are shown. The maintenance programmer must diagnose.
- 500 Same as error 260 but in the CHKADM routine.
- 510 Same as error 410 but in the CHKADM routine.
- 520 The number of cells available in the window array plus the next available storage cell less one is greater than the cell number of the first open window. The values of the first open window cell number, the next available storage cell, and I and K are shown. The error occurred in the CHKOVL routine. The maintenance programmer must diagnose.
- 530 A value in the NAVLID array has gone negative in the CHKOVL routine. The value and I, J, and K are shown. The maintenance programmer must diagnose.

The following message can also occur:

THERE ARE LESS THAN 'x' SENSORS IN THE STRING. THERE ARE 'y'.

This error message is followed by a list of all sensors dropped from the string (signified by 1). The number of live sensors has gone below that asked for in cc 21-30, card 3.

ADDITIONAL INFORMATION

Appendix D1 shows the format of input data to the algorithm that come from sources other than the simulation model. Appendix E shows a fully setup data deck for executing the algorithm on the Rand IBM 360/65 installation from a data tape resulting from the simulation model of Appendix B. Appendix F contains the full source listing of the pattern detection algorithm.

Appendix A

RANDOM NUMBER SEEDS FOR THE SIMULATION MODEL.

The following is a list of random number seeds for use in executing the simulation model:

- (1) 2116429
- (2) 8108509
- (3) 4774245
- (4) 1797929
- (5) 4810853
- (6) 6837431
- (7) 9643937
- (8) 1517245
- (9) 1217421
- (10) 6184335

Appendix B

INPUT DATA DECK FOR THE SIMULATION MODEL

The following is a fully setup deck to run the simulation model on the Rand IBM 360/65 computer installation. The output data will be saved on tape number 002325 for later use by the pattern detection algorithm.

Appendix D1

THE INPUT TAPE FORMAT FOR THE PATTERN DETECTION ALGORITHM

If information from actual sensor data is to be input to the detection algorithm, the following format must be used:

Each logical record represents an activation and must be five words long sorted in ascending order on word 1.

Word 1--time of activation (decimal).

Word 2--sensor number of activation (integer).

Word 3--the integer 3.

Word 4--the integer 0.

Word 5--the integer 0.

The last three records of the file are special:

Record N-2 (same format)

Sensor 1--time of activation = time of last actual activation + 5.

Record N-1 (same format)

Sensor 1--time of activation = time of last actual activation + 10.

Record N (same format)

Word 3--the integer 9.

All other words, the value 0.

Appendix D2

THE OUTPUT FILE FORMAT CREATED BY THE SIMULATION MODEL

Each logical record is five words long and is sorted on the file in ascending order on word 1.

Word 1--time (decimal).

Word 2--sensor number if an activation, or number of trucks in the convoy if convoy has just entered the string (integer).

Word 3--type record code (integer):

1--convoy starts through the sensor field.

2--convoy leaves the sensor field.

3--false-alarm activation.

4--first vehicle of convoy passes the midpoint of the sensor.

5--last vehicle of convoy passes the midpoint of the sensor.

6--vehicle activation.

7--first vehicle of a convoy starts through a sensor.

8--last vehicle of a convoy leaves a sensor.

9--indicates last record of the file.

Word 4--convoy direction (integer 1 or 2).

Word 5--convoy number. Each convoy is numbered consecutively (1 to N) for each direction separately (integer).

The last three records are shown in Appendix D1.

Appendix E

INPUT DATA DECK FOR THE PATTERN DETECTION ALGORITHM

The following is a fully setup deck to run the pattern detection algorithm on the Rand IBM 360/65 computer installation. Tape number 002325 in this case contains the output activations of the simulation model, but it could contain actual activation data. (The format is described in Appendix D1 for actual data, and in Appendix D2 for simulation or experimental data.)
